1. Introduction

The report before you constitutes the result of a cooperative effort by H. Meijer, C. Weijs, R. Broekhoff, T. Schippers and myself to analyze the nuclear capabilities and intentions of the Islamic Republic of Iran. This assignment is part of the course 'Methoden en Vaardigheden' given by the Institute for Interdisciplinary Studies which is part of the University of Amsterdam. The material here has been produced by applying the methods and techniques made available in the course to process open source intelligence. A choice has been made to report the results of the analysis rather than the learning process that has led to it in order to increase the clarity of the report; where important developmental issues in our process of analysis relate directly to the results they have been added to provide insight for the reader.

The structure of this report is based on the organization of the 'Analysis of Competing Hypotheses' technique as put forward by Richards J. Heuer Jr. in 'Psychology of Intelligence Analysis' (1999), in which the most important uncertainties are defined, hypotheses for the relevant possibilities are generated, an attempt is made to disprove them is made and the results are compared to determine the relative likelihood of the hypotheses. This technique is the basis for our analysis and the chosen structure allows for evaluation of each separate element in reaching our conclusion.

Note: in the text, frequent reference is made to nuclear weapons. To improve readability, this term has been replaced by NW's and refers to armaments that have a detonation capability based on a fission or fusion reaction. So-called dirty-bombs or radiation spreading conventional weapons are not included in the definition.

2. Theoretical framework and generation of hypotheses

To begin our analysis a basic understanding of the subject involved and our directive for analysis was required. A rudimentary research question was provided with our assignment and stated a three issues to focus on: Iran's drive to obtain NW's, their ability to build and use them and their intentions to use them if able to. In the process of analysis it became necessary to revisit and more clearly define this question, which resulted in the following formulation:

1. Does the I.R. of Iran have the intention to be capable to deploy NW's?
2. Does the I.R. of Iran have the capability to deploy NW's?
3. Does the I.R. of Iran plan to deploy NW's?

It can be derived from the questions that a choice was made to direct our analysis to the risk of military use of NW's. By aligning our questions and definitions along an axis that leads directly to that risk we evened the field for factors essentially equal in importance, such as construction and acquisition of NW's. A question could be posed as to the bias of our research alignment; alternative developments such as increased regional instability and diplomatic turmoil could receive less attention due to a predisposition to military use. Although the criticism is valid, we have nonetheless chosen for this alignment because it is focused on the the greatest impact and uncertainty issue and the method allows for other possible developments that fall either within the studied field or stretch into the peripheral to be highlighted and when necessary expanded upon in the process. As an example, diplomatic use is mostly covered in the second question as capability is the central issue of this development. Aligning to a threat other than military use however would reduce our focus on it and thereby the quality of our analysis of the factors involved, constituting a bias that forms a threat itself. Developmental branching from our alignment are an integral concept in this analysis and where relevant or expected to occur it will be discussed.

With the research question posed we undertook some basic research to get acquainted with the Republic of Iran, the field of nuclear technology and any peripheral information related it. After sharing the information found and discussing our views we began constructing a theoretical framework to serve as a map for our analysis. It can be found in Annex 1 and it consists of details of possible outcomes of our analysis, the sequencing or relations between them and the breadth of alternatives for each. The diagram serves vertically as a hypotheses-generating flowchart and horizontally as a step-by-step opening of possibilities for each element of detail. While both the downwards and planar expansions were filled by creative work based on our understanding of the subject, the systematic nature of the diagram us a chance to consider each step separately and expand it as fully as we could by means of both creativity and logical analogy. It increased clarity, provided integration or differentiation of fields of possibility and detail and an enhanced perception thereof, assessed the significance of possibilities as related to our analysis directive and overall lead to a growth of our understanding of the theoretical backdrop of our analysis. In the framework key nodes can be identified for directed data gathering and assumptions and elements of hypotheses can be checked for alternatives. However, although significant in its effect on our understanding, the sheer amount of hypotheses it can generate relieve it of any direct practical value in the ACH process, serving merely as a tool for clarification. From it, a central issue had to

be defined from which to generate a small number of relevant, integrative hypotheses. For this we used the method of uncertainty and impact plotting, where relevant uncertainties are assessed for possible impact and the greatest two selected. They are formed into axes with opposing possibilities for the uncertainties on opposing ends and crossed to form a schematic that holds the four possible configurations of these uncertainties in it's corners. They represent four scenarios that need to be analyzed and checked for relative likelihood which is what the ACH technique facilitates. We first constructed three impact / uncertainty schemata based on our threefold research question that quickly proved to be equally impractical. After some creative work we formulated a new governing schematic which represented our research questions, produced our main hypotheses and refined our research question. The horizontal and vertical axes represent the two uncertainties with the most severe possible impact for this analysis, relating to the first and third parts of our research question. Since the hypotheses are developmental orientations, directions in time rather than momentary images, only the driving forces are included as uncertainties. The capability of nuclear weapon deployment, the second part of our research question, is a threshold moment crossed over as the attempts to acquire NW's progress. It represents a transition in focus of uncertainty from activities in acquisition to intention of deployment for our analysis and links the two axes as a signature event on the trend towards an increasing threat.

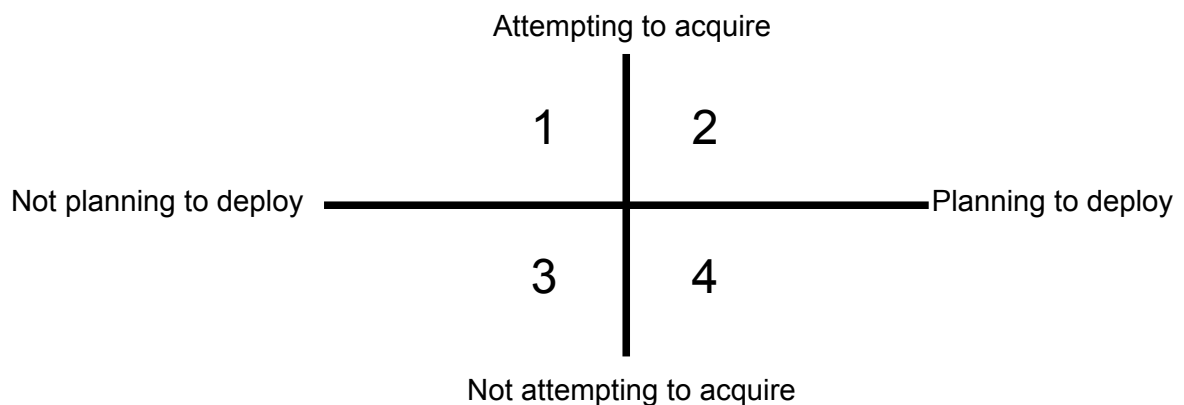

Figure 1: Uncertainty and hypotheses schematic.

The numbers in figure 1 are four of the hypotheses that will be tested, compared and evaluated in this analysis. From the renewed schematic a new subject definition for our analysis was created and it also lead us to revisit our research questions. At the start of the analysis we had been provided with a rudimentary threefold research question and although it had proven sufficient for a basic review of the subject matter, we soon encountered problems due to ambiguity of definition and direction of research. For example; the definition of 'use' could imply use as a tool of diplomatic pressure or deterrence creating a discussion about the relative weight of evidence in relation to 'use'. As a result the preliminary form was reformulated an replaced by the form as stated earlier this chapter.

With our field of study mapped and defined and aligned we proceeded to determine what possibilities were not yet covered and needed consideration to confidently start building hypotheses for our analysis. Two wild cards were introduced that represented integrations of the unexplored fields of possibilities as left out by our two main uncertainties: one was concerned with

the option that the I.R. of Iran was offered a ready-to-fire weapon and the means to deploy it, bypassing the question of capability in a seemingly invisible manner; and one entailing proliferation of a nuclear weapon by the I.R. of Iran, thereby making our analysis of their intentions irrelevant. They are hypothetical events as opposed to the developmental trends that constitute our main four hypotheses but they will be analyzed and compared with the same techniques.

The six hypotheses that resulted were expanded upon to improve our understanding of factors involved such as trends, signature events, relation to evidence and what signals to actively look for. They can be found in Annex 2 and will be summarized here. In reading these hypotheses, please take note that deployment includes employing an agent such as a terrorist organization as long as it is operating under Iranian imperative.

Hawk

The Islamic Republic of Iran is actively seeking to acquire or develop NW's and the means to deploy them aggressively. When successful, Iran will proceed to deploy these weapons.

Chess

The Islamic Republic of Iran is actively seeking to acquire or develop NW's and the means to deploy them defensively. When acquired they will not seek to actively deploy them but rather use them as a deterring measure and diplomatic tool.

Bluff

The Islamic Republic of Iran is not actively pursuing to acquire or develop NW's and the capability to deploy them. However, if an opportunity for acquisition presents itself Iran will make use of it and proceed to deploy them.

Dove

The Islamic Republic of Iran is not actively pursuing to acquire or develop NW's and the capability to deploy them. If an opportunity for acquisition presents itself, Iran will not make use of it.

Wild Card 1: Trumps

The Islamic Republic of Iran is offered a ready-to-fire nuclear weapon, possibly in addition to the means to deploy it.

Wild Card 2: Waldo

The Islamic Republic of Iran proliferates a nuclear weapon to a third party. This party uses the weapon in accordance with its own agenda.

3. Key elements

In the framework we could identify the details and related uncertainties that required evidence to distill certainty from them. However, time and access to information were limited and quantity of information does not necessarily improve an analysis. In stead the central key elements had to be defined, resulting in the signature events and warning signals that were discussed in Annex 2 as well as several assumptions deemed applicable and the noteworthy absence of certain evidence. A directed search was performed to fill in as many blank spots in our knowledge of these key elements as possible with a predominant focus on disproving evidence. The expected difference in information culture between numerically verifiable data and the more intangible information about intentions did not amount to the latter being more difficult to find but to it being less reliable, even when assessed in interrelated grids. A greater quantity of information relating to intentions was processed to produce information on par with the numerical data in terms of reliability and some was found for most key elements. The summarizing tenets of these key elements will be outlined below.

Note: due to the educational and short-term nature of this assignment, the data is sparse and relatively unreliable. The main focus of this report is on the analysis techniques used.

1. A nuclear infrastructure is emerging and although geared to nuclear energy for civilian use, when upgraded with more advanced techniques it can form the basis for a NW's construction capability (source 38, etc.).
2. The information requirement for such an infrastructural upgrade is partly already available to the Iranian government and military; several sources further imply that this knowledge is either growing or complete (sources 1,5,3,12,13,14,32, etc.).
3. The absence of nuclear testing by either Iran directly or other nations and groups that might participate in a NW's development program strongly suggests that Iran has not yet developed its own production of NW's (source 37).
4. With frequent IAEA inspections Iran is not reasonably able to hide a NW construction program. In order to realize such a program, the inspections would have to be denied access to the country (source 1 through 5, etc.).
5. Transactions have been made with Abdul Qadeer Khan through which technology for the production of NW's has come into Iranian hands (source 23 through 28, etc.).
6. Transactions have been made with the Toronto Man who has consequently been convicted of shipping equipment that facilitates the enrichment of Uranium to Iran (source 3). This implies both an incomplete NW's program and the intention to complete it.
7. The cultural and ethical climate in Iran does not idealize (nuclear) war or heroic suicide and it is reasonable to assume that Iran's regime conducts its affairs logically and ethically from their perspective of friendly and hostile relations (source 20,21, etc.).

Equally important is the absent key information, the evidence we would expect to see in case certain important possibilities were true:

1. Clear signs of hostility towards the USA, Israel or other countries
2. Clear signs of third party involvement with the exception of the Toronto Man and Khan
3. Clear signs of ethical or sanity-related divergence from 'Western' standards

We proceed by listing our own assumptions:

1. The absence of both any significant change in diplomatic stance or rhetoric and an open declaration of nuclear capability suggest that Iran has not yet developed or acquired NW's. We consider the benefits of hiding a nuclear capability to be outweighed by the lack of deterring effects in Iran's case.
2. Iran will not risk open death to its own people by initiating a (nuclear) war.
3. Iran perceives a threat to its security in the Middle-East turmoil from both neighboring countries, Western involvement in the region and expected oil shortages.
4. Iran does not greatly value a positive relationship with America, Israel or other affiliated factions due to, among other reasons, their involvement in the deterioration of order in the Middle-East.
5. The denial of full access to IAEA and other inspections is a result of Iran's motive to keep certain key elements of its (military) industry hidden, presumably to be more able to defend against any military actions and to reduce their transparency and vulnerability to the rest of the world.

These are the general topics of our database of evidence. A more detailed list can be found in the sources annex (4) and chapter on matrix generation.

Here it should be noted that many factors such as deception assessments, interrelations of uncertainties with political, economic and other developments as well as the possibilities of incomplete or misperception become significant. It is not impossible to expand the analysis to cover these as well or to integrate with other studies that detail them. However, although crucial in any real intelligence analysis, it reaches well beyond the scope of this paper to do so and we will continue with the subject matter as mapped this far.

4. Matrix generation

We continue our analysis by placing the results of the two previous chapters, the hypotheses and key elements in an ACH matrix to be correlated which can be found in Annex 3.1. In it the evidence has been given reliability assessments based on short background checks for the reporting actor, our estimation of the distance of the reporting actor to the information reported and an assessment of the probability that the information proves that which it suggest to be proving. For each row of evidence, marks were placed where they crossed the hypotheses columns. This has been done by means of a probability assessment in which the pluses and minuses represent the probability of that evidence surfacing if the hypothesis holds true. If there is no or very little relation to the hypothesis the field is left blank. The relative weight for the evidence per hypothesis will be assessed later when we assemble all the evidence for each hypothesis separately and draw our tentative conclusions.

In assessing the diagnostic value of our evidence, three items clearly stand out:

The item described as: 'Nuclear energy generation is a logical or even necessary step for Iran' has no diagnostic value in this matrix since it does not constitute evidence against any of the hypotheses. However, the reverse would have been very significant and we included it to clarify that uncertainty.

The item described as: 'Iran has the technical capability to create Plutonium' only has diagnostic value in disproving the evidence that Iran is not capable of creating weapons-grade fissile material; furthermore it hints at alternative explanations for the shipments from the item below.

The item described as: 'Khan and the Toronto Man sold NW's technology to Iran' forms, although the exact implication is under debate, very strong evidence that the Dove and Bluff hypotheses are not likely.

Before we can begin to assess the relative likelihood of the hypotheses, we must first realize the implications of this matrix and make any necessary adjustment.

5. Matrix refinement

Throughout our analysis process, many adjustments and refinements have been made. While the matrix has also undergone many updates, they were part of developments that had its effect on every part of the report here before you. The entire analysis has provided many moments of realization for us resulting in an equal number of improvements; to relate them all or structure this report to include them would be nigh near impossible. Constant recalibration and comparison to the literature and theory accompanied our analysis and will probably provide opportunities for refinement until well after the report is delivered. The contents of this chapter are therefore behind and spread throughout the report, not confined here.

6. Tentative conclusions

Here we will assess each hypothesis separately and draw preliminary conclusions as to their relative likelihood. A schematic of evidence organized per hypothesis can be found in Annex 3.2.

Hawk

The evidence stating that Iran is unable to develop a NW construction capability prevents this hypothesis from maturing but does not disprove it, especially when considering that it does not cover acquisition or bi- and multilateral developments which have not been disproved. However, we consider it unlikely that Iran will deploy NW's based on analyses of the humanistic and ethical climate in Iran, the qualities of it's leadership as demonstrated by the developments of the last decades and the absence of signs of preparation for war. As a result we estimate the relative likelihood of this hypotheses to be reasonable to low.

Dove

The most significant evidence disproving this hypothesis is that which states that Iran has made transactions of nuclear weapons technology with Khan and the Toronto Man. Although a possibility exists that these are hoaxes created to gain leverage for enforced inspections, it nevertheless strongly points to an active nuclear program. Furthermore, no clear signs of hostile intent have been found and the possibility of peaceful intentions can not be rejected. As a result we estimate the relative likelihood of this hypothesis to be somewhat low.

Bluff

The evidence implying an active nuclear program disproves Iran's supposed incapability or unwillingness to pursue NW's development. Combined with our assessment of Iran's intentions as described under Hawk, it leads us to estimate the relative likelihood of this hypothesis to be low.

Chess

As with Hawk, the evidence stating that Iran is unable to develop a NW construction capability prevents Iran from developing military nuclear capability on domestic soil, yet it does not prevent acquisition or bi- and multilateral developments and also does not disprove that Iran seeks to achieve the mentioned capability. Furthermore, signs of hostile intent have not been observed and we can not disprove a peaceful intention. This leads us to estimate the relative likelihood of this hypothesis to be high to reasonable.

Trumps

Alarmingly, we found very little evidence that disproves or prevents this hypothetical development. Since we assess the acquisition of NW's not to be in conflict with prevailing ethics the only evidence that could disprove this hypothesis is the state of the nuclear black market. In the absence of a more thorough analysis of the aforementioned market we estimate this hypothesis to

be high to reasonable.

Waldo

Our assessment of the sanity and ethical convictions of Iranian leadership is the only evidence disproving the possibility for this hypothetical event. An assessment of security protocols for Iran's nuclear armaments could complement this but is unavailable so we used information on intentions to reach the estimation that the relative likelihood of this hypothesis is sub-reasonable to low.

A reference to our research questions can be made here: we tentatively conclude that it is likely that Iran has the intention to be capable to deploy NW's, unlikely that they have the capability to do so yet and unlikely that they will deploy them if acquired. This results in a tentative **conclusion that the Chess** scenario is most likely and a note to further study the nuclear market and if in any way possible Iranian military security protocols to better ascertain the likelihood of the two wild cards. In the absence of such study we tentatively conclude the hypothetical Trumps event relatively likely to occur.

7. Sensitivity analysis

To test our tentative conclusion, we will determine the sensitivity of our judgement. Our tentative conclusion depends on a few crucial pieces of evidence and estimations that could be wrong, incomplete or misinterpreted. They are most notably the following:

- Iran's active pursuit of military nuclear technology as exhibited by transactions with Khan and the Toronto Man and other evidence
- Our assessment of analyses of Iran's ethical climate and the sanity of its leadership
- Iran's inability to covertly construct a NW production capability on domestic soil due to frequent inspections

These three items relate to the three parts of our research question. The hypotheses are also composed of unique combinations of answers to these research questions since they were generated from a schematic created from these questions and any change in an answer to one of the questions would correspond with a shift between the four hypotheses, the wild cards responding mostly to intentions and some external factors.

The evidence pertaining to Iran's pursuit of military nuclear technology could be wrong. We could pose that the incidents were fabricated to harm Iran or create leverage for enforced inspections to reduce nuclear threat, which we do not consider to be very unlikely, or that elements within Iran operated independent of its government. There is however more evidence to disprove the possibility of Iran not pursuing an NW production capability. If this were nonetheless false, misinterpreted or otherwise wrong, it would result in a shift towards Bluff and Dove and change our estimation of the Dove hypothesis to state it has the highest relative likelihood.

To detail this for each of the three above stated items separately: if our assessment of Iran's ethical climate and the sanity of its leadership is off the mark, all conclusions of intention would need to be revised since they depend almost completely on it. Trumps and Waldo would become more likely and the Hawk scenario would need to be added to our conclusion as a close second in the list of likely hypotheses.

Lastly, if Iran's supposed inability to build a nuclear weapon production capability due to frequent inspections does not hold true and Iran could still conduct a (covert) nuclear development program while being inspected, it would increase the developmental speed of both Chess and Hawk and allow the possibility of these two hypotheses to fully develop. A critical note here relates to the possibility of acquisition or bi- and multilateral developments in NW technology, which does not disprove this statement but bypasses it with the same effect. Furthermore, the hypothetical Waldo event would become more likely in both cases as Iran would need to have NW's to proliferate them.

The reliability of these three key items has respectively been evaluated as A3c, Bc3 and A1c, implying that the second has the highest chance of being off mark, followed by the first. The second item is based on two different external analyses, the third on over four different external assessments and the third on two pieces of evidence directly and several other pieces that include

elements that disprove the possibility of Iran not pursuing a NW production capability. Combined with the reliability of evidence, we come to the following sensitivity assessment:

- Our conclusion is most sensitive to errors relating to our assessment of Iran's ethical climate
- Our conclusion is less sensitive to errors in our assessment that Iran is unable to create a NW production capability on domestic soil.
- Our conclusion is even less sensitive to errors in our deduction that Iran is pursuing a NW development program

To qualify these sensitivities, we consider the chance of error in the first item to be small, in the second two to be very small and in the third to be minute.

8. Conclusions

Before stating our conclusion, we will make a note as to the certainty of intelligence estimates in general. Because of the nature of the availability of information, the information itself and the complexity of our topic, a different probability ratio prevails in risk assessments than that common in legal matters or exact science. The chance of deducting the existence of patterns that do not exist, the alpha-chance, rates at 20-30 percent in this discipline as opposed to 0.1 and 5 respectively for those in law and science, mainly due to the wealth of information available and lack of clear patterns in it. The chance of not detecting a pattern or Beta-chance for our discipline is rated at 5 percent, equal to legal matters and well above that of exact science which sets it around 20 percent. The chance of any hypothesis to escape our attention is 5 percent and the chance of stating a hypothesis that doesn't exist is 20 to 30.

This implies that our conclusion must be perceived and applied differently than conclusions from the disciplines above. We urge you to realize that our assessment of restrictions, curbed possibilities and resulting indication of impossibilities are the main tenet of our analysis, not the possibilities that have been found yet not disproved. Although the latter constitute the most likely hypotheses to be true, they have in no way been proven and serve only as an indication of what is possibly, and to a certain extent probably, true. With that stated we report the following conclusion.

Based on the intelligence gathered and processed, we conclude with a high level of certainty that Iran is currently attempting to achieve a military nuclear capability. With slightly less certainty we conclude that Iran has not yet realized this, but due to the possibility of black market acquisition and joint development ventures with third parties Iran could do so in a relatively short timespan. This needs to be integrated with further study of the nuclear black market.

We further conclude that if Iran attains military nuclear capability, they will not aggressively deploy the nuclear weapons. We state this with less yet still firm certainty. Any change in regime or military leaders could affect this conclusion and needs to be closely observed.

The possibility of nuclear proliferation in case Iran attains military nuclear capability is rather improbable and we conclude this with a certainty more or less equal to that of our previous statement. This however also depends on Iranian ability to prevent unwilling proliferation through theft and accident.

We base these conclusions on the evidence gathered, the non-information deduced from our theoretical framework and those assumptions that we deemed reliable that we processed with the Analysis of Competing Hypotheses technique. Although the reliability of our evidence and our implementation of technique is imperfect, we give our confidence to these conclusions and consider them to be most certain analysis possible with our current level of information and analysis technique.

Our conclusion is however sensitive to error and therefore the alternative conclusions shall be given as well. First is the option that Iran will complete its nuclear program and make aggressive military use of its weapons, which was rejected on our assessment of the ethical character of Iranian culture and leadership as well as a lack of signs to be expected in case this hypothesis

would prove to be true. Second is the option that Iran is pursuing a peaceful civilian nuclear energy program, which we rejected mainly on the basis of transactions with Khan and the Toronto Man and assorted external assessments. Third and last is the option that Iran wishes to acquire nuclear capability out of an aggressive impulse but is as of yet unable to pursue this. We rejected this due to both the mentioned assessment of ethics and nuclear technology transactions.

9. Milestones

Some items are worth noting for future observation due to their significance in determining the state of the situation and possible changes therein. If evidence surfaces of Iran or and perhaps less so a third party having nuclear capabilities, it could prove to be a result of the effectuation of one of the wild card hypotheses. Other events to be noted are regime instabilities or turmoil within military ranks, as it could lead to a changing climate of intentions. The level of access granted to IAEA and other inspections are an important clue in determining the state of nuclear technological advancement and the existence of a development program on domestic soil. The nuclear black market must also be kept under close observation for both the possibility of Iran attaining nuclear capability through it and the possibility of deducing the state of Iran's aspirations and abilities in the field of nuclear development. Lacking security measures for nuclear facilities in Iran could lead to proliferation and need to be observed closely.

Lastly we can note that in case the Chess scenario holds true, the motive is most likely establishing means of deterrence and a last line of defense and attainment of regional dominance. Information as to what in Iranian views constitutes the last line in a last line of defense is also an important issue: perhaps in their mindset a regime change towards other leaders, democracy, secularism, another form of Islam or another religious orientation could be interpreted as the end of the nation and trigger this defense policy.

Annex 2 Scenarios

Hawk

The Islamic Republic of Iran is actively seeking to acquire or develop NW's and the means to deploy them aggressively. When successful, Iran will proceed to deploy these weapons.

The central pattern of this hypothesis is an aggressive intention and a trend towards increasing threat of military use of NW's. Considering the consequences of this course of action the possibility of mental instability in Iranian leaders is very real, making logical human factoring near irrelevant. The speed by which this hypothesis develops itself can be checked by efforts to restrain their ability to gather and construct nuclear technology but there are several ways in which these restrictions can and have been bypassed.

Important uncertainties in this hypothesis are the state of nuclear development, the state of the nuclear black market, Iranian ability to conceal a NW's program, relationships with other groups or nations in a joint nuclear development venture, the mental state and stability of the regime, possible third parties behind the scenes, Iran's ability to either deliver a nuclear payload or have it delivered and possibly their ability to devise a plausible scenario for denying involvement, although it should be considered that they might not make one.

Signature events are signs of an aggressive nuclear development policy, negligence or severe deterioration of diplomatic activities, signs of exercises, preparations, stocking and maneuvering as a prelude to war and the actual appearance or detonation of a nuclear weapon somewhere in the world.

Other less immediate warning signals are not unlike those of other scenarios and events that separate this hypothesis from the others must be sought. It is however likely that Iran will make great effort to keep these hidden and they will be quite rare. Examples are actual plans or orders for a nuclear war

Chess

The Islamic Republic of Iran is actively seeking to acquire or develop NW's and the means to deploy them defensively. When acquired they will not seek to deploy them but rather use them as means of deterrence and as a diplomatic tool.

The central pattern of this hypothesis is an intention to safeguard the state and an attempt to do so without provoking violent action or being stopped. The trend is a cautious proceeding while keeping relations amiable or at least non-aggressive. The hypothesis will most likely develop at a lesser speed than Hawk due to the caution applied and might even halt out of necessity.

Important uncertainties in this hypothesis are the same as with Hawk although some in a different light: the state of nuclear development, the state of the nuclear black market, Iranian ability to conceal a NW's program and relationships with other groups or nations in a joint nuclear development venture are similar. The mental state and stability of the regime, possible third parties behind the scenes, Iran's ability to either deliver a nuclear payload or have it delivered and development efforts therein are judged in a different way: any signs of a developing of other than national defense delivery systems are proof that this scenario may have been left behind.

Signature events are signs of an nuclear development program, positive and calming diplomacy that can not appear to friendly to not lose respect of allies and harvest distrust, absence of exercises, preparations, stocking and maneuvering as a prelude to war and the actual declaration of nuclear capability without intent of war.

Other less immediate warning signals are not unlike those of other scenarios and events that separate this hypothesis from the others must be sought. It is however likely that Iran will make great effort to keep these hidden and they will be quite rare. Examples are actual plans or orders for a nuclear war

Bluff

The Islamic Republic of Iran is not actively pursuing to acquire or develop NW's and the capability to deploy them. However, if an opportunity for acquisition presents itself, Iran will make use of it and proceed to deploy the weapon aggressively.

Logically we would assume that the lack of active pursuit implies a constrained ability to develop or acquire NW's such as insufficient funds or sabotage, and not a lack of motive. However, the possibility of a lack of motive to develop the weapons combined with a motive to nonetheless deploy if able to must be considered as well.

The central pattern of this hypothesis is either an inability or disinterest to achieve nuclear capability. The latter has no trends although we might observe an attempt to enhance status and create a form of deterrence by suggesting a nuclear development program and capability and the relation to nuclear black market activity must be closely observed. The first pattern has a main trend, to open the possibilities for commencing a nuclear program or acquiring one. The developmental speed, although less then that of Hawk due to the restrictions on nuclear pursuits, will be high due to the aggressive intent. Unchanged the hypothesis is an incubation stage for Hawk, although any other scenario can also follow from Bluff.

Important uncertainties in this hypothesis are Iranian abilities to start a NW's development program such as finances and freedom from inspections, the state of nuclear development, Iranian ability to conceal a NW's program, relationships with other groups or nations in a joint nuclear development venture, the mental state and stability of the regime, possible third parties behind the scenes, Iran's ability to either deliver a nuclear payload or have it delivered and especially the state of the nuclear black market, since the restrictions that prevent them from commencing a weapons program do not apply the same way to the possibility of acquisition. Another uncertainty that can be highlighted is why Iran, while unable to develop NW's, would suggest this nonetheless. The most likely explanations are prestige and deterrence but a possibility of a sincere expectation of large-scale conflicts exists.

Signature events are signs of either a lack of motive to develop NW's or an aggressive motive combined with lacking, foiled or incomplete effort to actualize that motive. Efforts to relieve constraints could be noted depending on the restrictions; increased contra-espionage efforts or a reorganization of state expenses are examples. Diplomacy would either remain the same in the case of lack of ability or inclined towards intimidation in case of nuclear suggestion. It must be attempted to clearly note the moment this scenario changes since it might take a flight as Hawk.

Dove

The Islamic Republic of Iran is not actively pursuing to acquire or develop NW's and the capability to deploy them. If an opportunity for acquisition presents itself, Iran will not make use of it.

The main pattern here is a stance of peaceful development. Whether out of idealism or fear of repercussions, Iran is actively taking a position against arming itself with nuclear capability. The developmental trend is a growth of civilian nuclear technology at reasonable speed whilst Iran will make sure the rest of the world knows it is done with a peaceful intention by allowing inspections of third parties. It will nevertheless be a challenge to build trust due to the amount of mistrust in the political arena and since Iran can not allow the inspections full access due to domestic safety concerns and other issues.

Important uncertainties in this scenario are the reasons for not attempting to acquire NW's, their relationship to the factors involved in doing so to properly assess the possibility of a scenario switch, Iranian abilities to start a NW's development program, the state of civilian nuclear development, Iranian ability to conceal a NW's program, relationships with other groups or nations in a joint nuclear development venture, the mental state and stability of the regime in terms of the realism of a positive peaceful stance and possible third parties behind the scenes.

Signature events are signs of compliance and transparency from Iran, responses to engineered or observed opportunities to start developing NW's, and the end of active development when a certain civilian capability is attained. We reiterate here that close observation is required since the outwards appearance of this scenario is very likely to be used as a cover in case any other scenario is being actualized with Iran presumably taking great caution to not break the illusion. On the other hand, evidence such as the nuclear black market transactions that Iran has made could have been created to open the possibility of deeper inspections and increase world safety even if this scenario is true.

Wild Card 1: Trumps

The Islamic Republic of Iran is offered a ready-to-fire nuclear weapon, possibly in addition to the means to deploy it. This could be through the black market or directly through another state or group and will most likely be a hidden event.

The main pattern is a sudden change of factors involved in the threat assessment with a high chance of not being observed. It has a very high developmental speed, perhaps less than a day, and facilitates a sudden switch in scenarios whilst removes the possibility of Dove and Bluff. It can also lead directly to the second wild card but the resulting sequence would be black market trading with Iran being one of the many actors, rendering it less than directly relevant our analysis. Being offered the means to construct a weapon rather than the weapon itself would constitute third party help in any of the other scenarios and is not covered in this scenario.

Important uncertainties in this hypothesis are the state of the nuclear black market, willingness of other states or groups to offer Iran a weapon, Iranian ability to acquire and afford a nuclear weapon and Iran's possible efforts to create opportunities for acquiring NW's such as encouraging

possible sellers to obtain a weapon.

Signature events characterized by the short time-scale: unexpected shifts in diplomatic stance and public declarations, infrastructural changes and military reorganizations, signs of nuclear capability so out of sync with known developments to be deemed erratic if this wild card was disregarded and the disappearance of a nuclear weapon from the black market or any other source.

A close connection obviously exists with analyses of illegal arms trade and security operations on the black market, which also have this relevance to our next wild card.

Wild Card 2: Waldo

The Islamic Republic of Iran proliferates a nuclear weapon to a third party. This party uses the weapon according to its own agenda.

The main pattern is either a lack of competence in preventing non-intentional proliferation or an active intent to disrupt world affairs, strengthen the position of a third party, target a shared enemy or in a variety of ways shifting political and military focus to another party. This scenario poses one of the greatest threats in this analysis since a third party could have far lesser restrictions on actual use of a nuclear weapon and it can follow or branch off from Hawk or Chess, rendering all assessments of intention from those scenarios irrelevant. The third party could employ the weapon in a variety of ways ranging from deterrence to terrorism, however the low visibility of proliferation and resulting problems in determining the party involved or the location of the weapon make any predictions of the planned use, if it even exists, very difficult.

Signature events are the disappearance of a nuclear weapon from Iran and signs or declarations of nuclear capability of a third party. Warning signals could include lacking quality of security measures protecting Iran's nuclear arsenal possibly related to an enforced secrecy, and signs of Iranian intentions of disrupting world affairs or otherwise pursue their agenda by proliferation.
